

- FILO — First-In Last-Out
- Implementation as Array or LinkedList

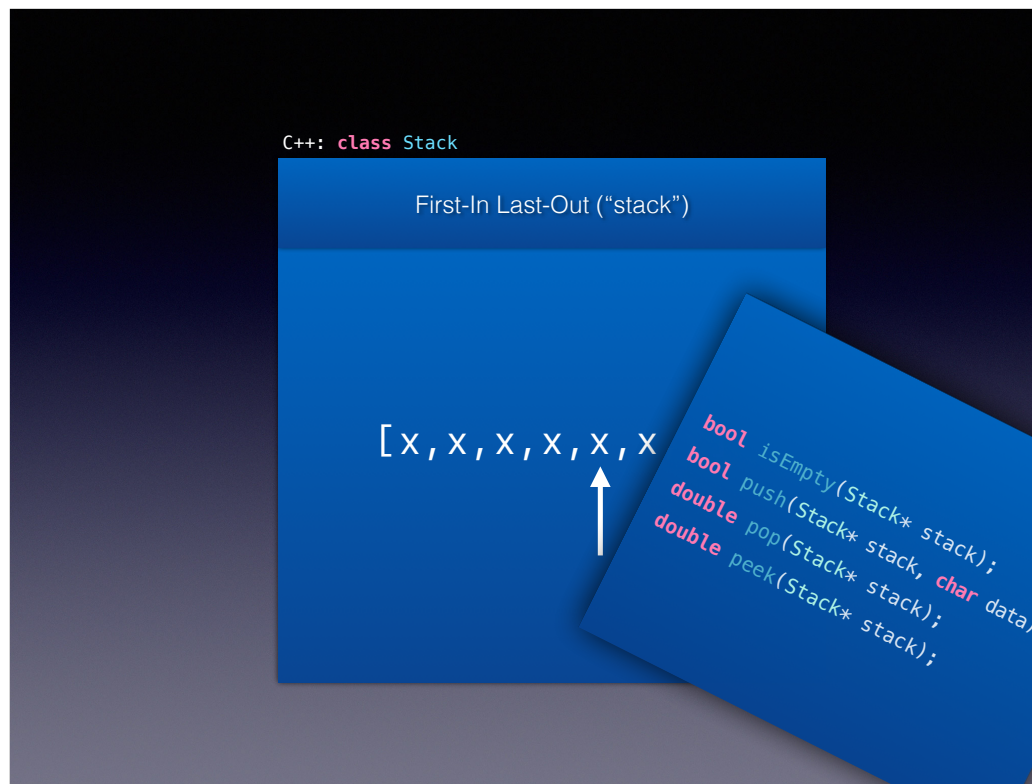

C++: `class Stack`

First-In Last-Out ("stack")

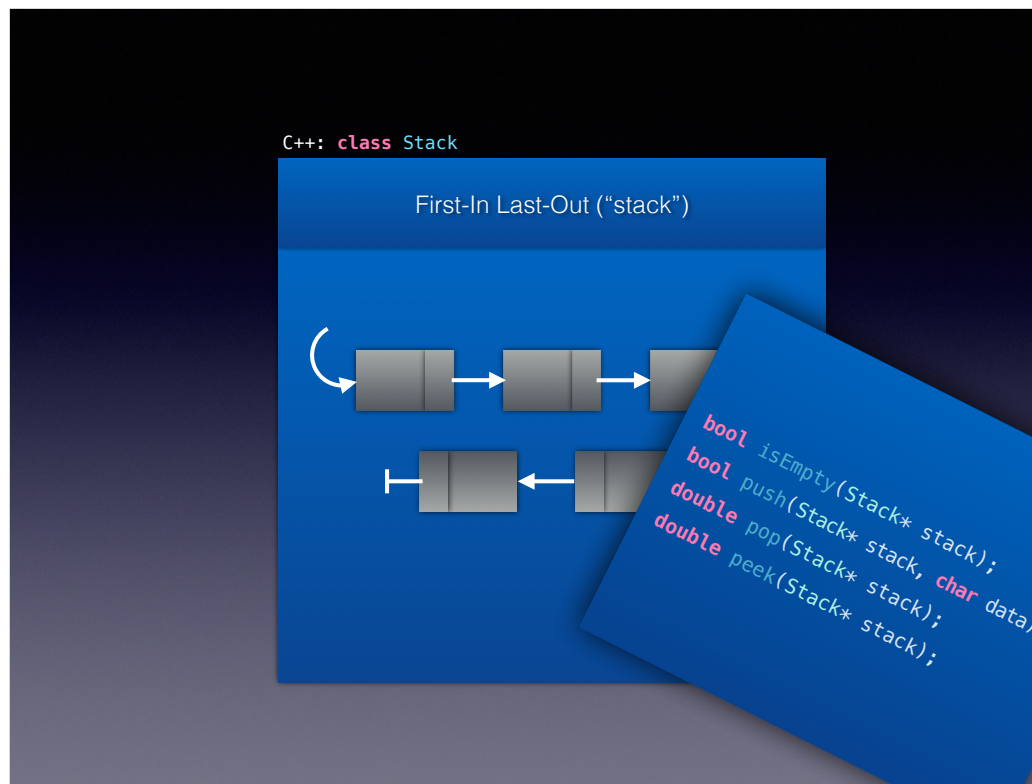

```
bool isEmpty(Stack* stack);  
bool push(Stack* stack, char data);  
double pop(Stack* stack);  
double peek(Stack* stack);
```

Here is a “class” called Stack, it is a data structure that implements the First-In Last-Out rule, also known as a Stack. There are some top-level functions that do stuff to the stack.

- isEmpty checks if the stack is empty.
- push adds an item to the stack. It returns `true` if it was successfully added, or `false` if it failed.
- pop deletes the top item and returns the value.
- peek “peeks” at the top item without deleting the value.

You could implement this as an array with a cursor variable...

Or as a linked list.

C++: `class Stack`

First-In Last-Out ("stack")

```
bool isEmpty(Stack* stack);  
bool push(Stack* stack, char data);  
double pop(Stack* stack);  
double peek(Stack* stack);
```

So, that's the difference between the specification, the methods or functions that are exposed, versus the implementation, or what is under-the-hood.

C++: `class Stack`

First-In Last-Out ("stack")

```
bool isEmpty(Stack* stack);  
bool push(Stack* stack, char data);  
double pop(Stack* stack);  
double peek(Stack* stack);
```

Let's look at how a stack could look if it was implemented as an array.

C++: **class** Stack

First-In Last-Out ("stack")

```
bool isEmpty(Stack* stack);  
bool push(Stack* stack, char data);  
double pop(Stack* stack);  
double peek(Stack* stack);
```

Implemented with Array

C++: `class Stack`

First-In Last-Out ("stack")

```
bool isEmpty(Stack* stack);  
bool push(Stack* stack, char data);  
double pop(Stack* stack);  
double peek(Stack* stack);
```

Implemented with Array

```
private:  
int currentIndex = -1  
  
isEmpty(stack) == true  
peek(stack) == CRASH
```

0	1	2	3	4	5

We have to keep track of a “private” variable, which is pointing to the current index. Don’t worry about what a “private” variable is yet, you will learn about that when Andy talks about encapsulation and object-oriented programming.

I’m going to keep track of the values of the functions, isEmpty and peek.

Now, I’m going to push a value to the stack, the letter ‘g’.

C++: `class Stack`

First-In Last-Out ("stack")

```
bool isEmpty(Stack* stack);  
bool push(Stack* stack, char data);  
double pop(Stack* stack);  
double peek(Stack* stack);
```

Implemented with Array

```
private:  
int currentIndex = -1  
  
isEmpty(stack) == true  
peek(stack) == CRASH
```

0	1	2	3	4	5

```
push(stack, 'g')
```

C++: `class Stack`

First-In Last-Out ("stack")

```
bool isEmpty(Stack* stack);  
bool push(Stack* stack, char data);  
double pop(Stack* stack);  
double peek(Stack* stack);
```

Implemented with Array

private:

```
int currentIndex = -1
```

```
isEmpty(stack) == true
```

```
peek(stack) == CRASH
```

0	1	2	3	4	5
g					

```
push(stack, 'g')
```

C++: `class Stack`

First-In Last-Out ("stack")

```
bool isEmpty(Stack* stack);  
bool push(Stack* stack, char data);  
double pop(Stack* stack);  
double peek(Stack* stack);
```

Implemented with Array

```
private:  
int currentIndex = -1  
  
isEmpty(stack) == true  
peek(stack) == CRASH
```

0	1	2	3	4	5
g					

```
push(stack, 'g')
```

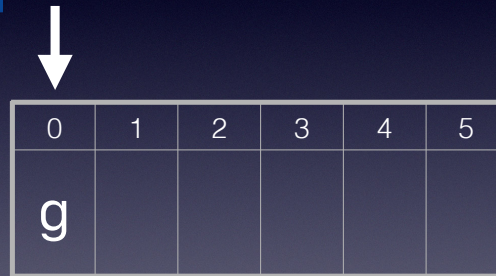

C++: `class Stack`

First-In Last-Out ("stack")

```
bool isEmpty(Stack* stack);  
bool push(Stack* stack, char data);  
double pop(Stack* stack);  
double peek(Stack* stack);
```

Implemented with Array

```
private:  
int currentIndex = 0  
  
isEmpty(stack) == false  
peek(stack) == 'g'
```

0	1	2	3	4	5
g					

```
push(stack, 'g')
```

You'll notice the variables update, I incremented the `currentIndex` and if I call `isEmpty` or `peek`, you'll notice that their values are also different now. For example, the `peek` function returns the value at the current index.

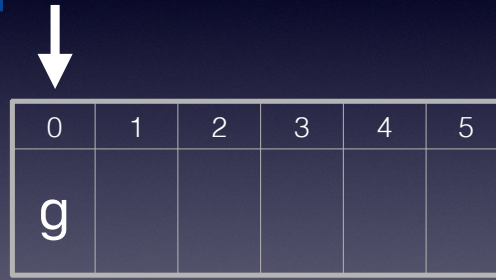

C++: `class Stack`

First-In Last-Out ("stack")

```
bool isEmpty(Stack* stack);  
bool push(Stack* stack, char data);  
double pop(Stack* stack);  
double peek(Stack* stack);
```

Implemented with Array

```
private:  
int currentIndex = 0  
  
isEmpty(stack) == false  
peek(stack) == 'g'
```

0	1	2	3	4	5
g					

```
push(stack, 'g')
```

C++: `class Stack`

First-In Last-Out ("stack")

```
bool isEmpty(Stack* stack);  
bool push(Stack* stack, char data);  
double pop(Stack* stack);  
double peek(Stack* stack);
```

Implemented with Array

0	1	2	3	4	5
g	a				

private:

```
int currentIndex = 1
```

```
isEmpty(stack) == false
```

```
peek(stack) == 'a'
```

```
push(stack, 'a')
```

Let's continue, I'll push 'a'

C++: `class Stack`

First-In Last-Out ("stack")

```
bool isEmpty(Stack* stack);  
bool push(Stack* stack, char data);  
double pop(Stack* stack);  
double peek(Stack* stack);
```

Implemented with Array

0	1	2	3	4	5
g	a				

private:

```
int currentIndex = 1
```

```
isEmpty(stack) == false
```

```
peek(stack) == 'a'
```

```
push(stack, 'a')
```

C++: `class Stack`

First-In Last-Out ("stack")

```
bool isEmpty(Stack* stack);  
bool push(Stack* stack, char data);  
double pop(Stack* stack);  
double peek(Stack* stack);
```

Implemented with Array

```
private:  
int currentIndex = 2  
  
isEmpty(stack) == false  
peek(stack) == 'r'
```

0	1	2	3	4	5
g	a	r			

```
push(stack, 'r')
```

'r'

C++: `class Stack`

First-In Last-Out ("stack")

```
bool isEmpty(Stack* stack);  
bool push(Stack* stack, char data);  
double pop(Stack* stack);  
double peek(Stack* stack);
```

Implemented with Array

```
private:  
int currentIndex = 2  
  
isEmpty(stack) == false  
peek(stack) == 'r'
```

0	1	2	3	4	5
g	a	r			

```
push(stack, 'r')
```

C++: `class Stack`

First-In Last-Out ("stack")

```
bool isEmpty(Stack* stack);  
bool push(Stack* stack, char data);  
double pop(Stack* stack);  
double peek(Stack* stack);
```

Implemented with Array

```
private:  
int currentIndex = 3  
  
isEmpty(stack) == false  
peek(stack) == 'r'
```

0	1	2	3	4	5
g	a	r	r		

```
push(stack, 'r')
```

'r'

C++: `class Stack`

First-In Last-Out ("stack")

```
bool isEmpty(Stack* stack);  
bool push(Stack* stack, char data);  
double pop(Stack* stack);  
double peek(Stack* stack);
```

Implemented with Array

```
private:  
int currentIndex = 3  
  
isEmpty(stack) == false  
peek(stack) == 'r'
```

0	1	2	3	4	5
g	a	r	r		

```
push(stack, 'r')
```

C++: `class Stack`

First-In Last-Out ("stack")

```
bool isEmpty(Stack* stack);  
bool push(Stack* stack, char data);  
double pop(Stack* stack);  
double peek(Stack* stack);
```

Implemented with Array

```
private:  
int currentIndex = 4  
  
isEmpty(stack) == false  
peek(stack) == 'e'
```

0	1	2	3	4	5
g	a	r	r	e	

```
push(stack, 'e')
```

'e'

C++: `class Stack`

First-In Last-Out ("stack")

```
bool isEmpty(Stack* stack);  
bool push(Stack* stack, char data);  
double pop(Stack* stack);  
double peek(Stack* stack);
```

Implemented with Array

private:

```
int currentIndex = 4
```

```
isEmpty(stack) == false
```

```
peek(stack) == 'e'
```

0	1	2	3	4	5
g	a	r	r	e	

```
push(stack, 'e')
```

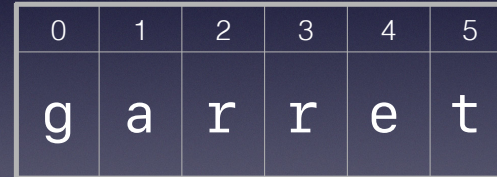

C++: `class Stack`

First-In Last-Out ("stack")

```
bool isEmpty(Stack* stack);  
bool push(Stack* stack, char data);  
double pop(Stack* stack);  
double peek(Stack* stack);
```

Implemented with Array

```
private:  
int currentIndex = 5  
  
isEmpty(stack) == false  
peek(stack) == 't'
```

0	1	2	3	4	5
g	a	r	r	e	t

```
push(stack, 't')
```

't'

Can anyone predict what the major con of using an array is?

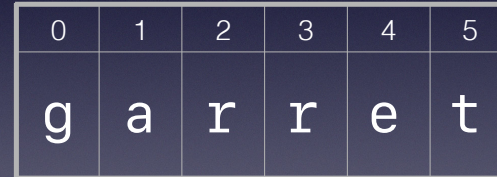

C++: `class Stack`

First-In Last-Out ("stack")

```
bool isEmpty(Stack* stack);  
bool push(Stack* stack, char data);  
double pop(Stack* stack);  
double peek(Stack* stack);
```

Implemented with Array

```
private:  
int currentIndex = 5  
  
isEmpty(stack) == false  
peek(stack) == 't'
```

0	1	2	3	4	5
g	a	r	r	e	t

```
push(stack, 't')
```

C++: `class Stack`

First-In Last-Out ("stack")

```
bool isEmpty(Stack* stack);  
bool push(Stack* stack, char data);  
double pop(Stack* stack);  
double peek(Stack* stack);
```

Implemented with Array

```
private:  
int currentIndex = 5  
  
isEmpty(stack) == false  
peek(stack) == 't'
```

0	1	2	3	4	5
g	a	r	r	e	t

⚠ This will crash

```
push(stack, 't')
```

It has a fixed size, if we try to push more, it won't work.

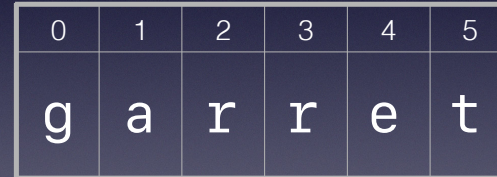

C++: `class Stack`

First-In Last-Out ("stack")

```
bool isEmpty(Stack* stack);  
bool push(Stack* stack, char data);  
double pop(Stack* stack);  
double peek(Stack* stack);
```

Implemented with Array

```
private:  
int currentIndex = 5  
  
isEmpty(stack) == false  
peek(stack) == 't'
```

0	1	2	3	4	5
g	a	r	r	e	t

```
push(stack, 't')
```

Ok, let's go back.

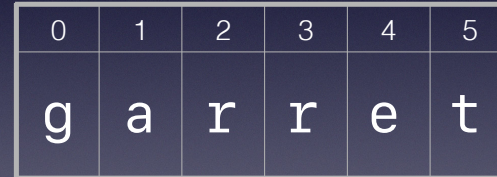

C++: `class Stack`

First-In Last-Out ("stack")

```
bool isEmpty(Stack* stack);  
bool push(Stack* stack, char data);  
double pop(Stack* stack);  
double peek(Stack* stack);
```

Implemented with Array

```
private:  
int currentIndex = 5  
  
isEmpty(stack) == false  
peek(stack) == 't'
```

0	1	2	3	4	5
g	a	r	r	e	t

`pop(stack)`

Now, let's try popping an item from the stack.

C++: `class Stack`

First-In Last-Out ("stack")

```
bool isEmpty(Stack* stack);  
bool push(Stack* stack, char data);  
double pop(Stack* stack);  
double peek(Stack* stack);
```

Implemented with Array

```
private:  
int currentIndex = 4  
  
isEmpty(stack) == false  
peek(stack) == 'e'
```

0	1	2	3	4	5
g	a	r	r	e	t

`pop(stack)` t

```
C++: class Stack
    First-In Last-Out ("stack")

    bool isEmpty(Stack* stack);
    bool push(Stack* stack, char data);
    double pop(Stack* stack);
    double peek(Stack* stack);

private:
    int currentIndex = 3

    isEmpty(stack) == false
    peek(stack) == 'r'

    pop(stack)    e
```

Implemented with Array

0	1	2	3	4	5
g	a	r	r	e	t

You'll notice that I'm not actually removing the values. Implicitly, we are marking each item as "deleted", or "garbage" since the `currentIndex` is less than it.

We don't need to delete the data, so we won't. Just decrementing the `currentIndex` variable is a lot faster than deallocating the space. This is similar to how your computer's hard drive works. When you delete a file, you aren't actually removing the file. Your computer will mark it as deleted, and when the time comes that you need to use that space, it just overwrites the "deleted" data.

C++: `class Stack`

First-In Last-Out ("stack")

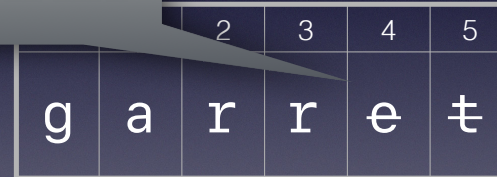

```
bool isEmpty(Stack* stack);  
bool push(Stack* stack, char data);  
double pop(Stack* stack);  
double peek(Stack* stack);
```

Implemented with Array

Implicitly, we mark these items as "garbage,"
since the current `currentIndex` is less than it.

```
private  
int currentIndex;
```

```
isEmpty(stack) == false  
peek(stack) == 'r'
```

		2	3	4	5
g	a	r	r	e	t

`pop(stack)` e

C++: `class Stack`

First-In Last-Out ("stack")

```
bool isEmpty(Stack* stack);  
bool push(Stack* stack, char data);  
double pop(Stack* stack);  
double peek(Stack* stack);
```

Implemented with Array

Implicitly, we mark these items as "garbage,"
since the current Index is less than it.

A benefit of using an array is we don't
need to deallocate data, we mark as
deleted and overwrite when needed.

Changing an integer value is faster
than deallocation.

2	3	4	5

C++: `class Stack`

First-In Last-Out ("stack")

```
bool isEmpty(Stack* stack);  
bool push(Stack* stack, char data);  
double pop(Stack* stack);  
double peek(Stack* stack);
```

Implemented with LinkedList

Do you want to use:

- ☐ singly-linked list
- ☐ doubly-linked list

C++: `class Stack`

First-In Last-Out ("stack")

```
bool isEmpty(Stack* stack);  
bool push(Stack* stack, char data);  
double pop(Stack* stack);  
double peek(Stack* stack);
```

Implemented with LinkedList

Do you want to use:

- ☒ singly-linked list
- ☐ doubly-linked list

First-In Last-Out ("stack")

```
bool isEmpty(Stack* stack);  
bool push(Stack* stack, char data);  
double pop(Stack* stack);  
double peek(Stack* stack);
```

First-In Last-Out ("stack")

```
bool isEmpty(Stack* stack);  
bool push(Stack* stack, char data);  
double pop(Stack* stack);  
double peek(Stack* stack);
```

Task 1: Implement a Stack using a singly-linked list in C.

First-In Last-Out ("stack")

```
bool isEmpty(Stack* stack);  
bool push(Stack* stack, char data);  
double pop(Stack* stack);  
double peek(Stack* stack);
```

Task 1: Implement a Stack using a singly-linked list in C.
Hint: Stacks only care about what's on top.

First-In Last-Out ("stack")

```
bool isEmpty(Stack* stack);  
bool push(Stack* stack, char data);  
double pop(Stack* stack);  
double peek(Stack* stack);
```

Task 1: Implement a Stack using a singly-linked list in C.

Hint: Stacks only care about what's on top.

Task 2: Write Unit Tests for the stack
